System Call: accept()

The accept() system call is used in network communication to accept incoming connection requests from client systems. In the context of LOCUS OS, this system call would play an important role in enabling communication between distributed nodes in the network.

When a process on one machine wants to establish a connection, the server process uses accept() to receive and handle that connection. This supports the distributed nature of LOCUS, where multiple systems interact and share resources.

Challenges in Implementation

Due to the lack of available source code and documentation, the exact implementation details of system calls in LOCUS OS are not accessible. Additionally, since the operating system could not be installed, practical demonstration of system calls was not possible.
